

Definite Integrals, Riemann Sums, and FTC

Douglas Meade, Ronda Sanders, and Xian Wu
Department of Mathematics

Overview

This lab will develop your understanding of the definite integral as defined and computed via Riemann sums and its connection with the indefinite integral (antiderivative) via the Fundamental Theorem of Calculus (FTC).

Maple Essentials

- Important Maple commands introduced in this lab are:

Command	Description	Example
<code>int(f(x), x)</code>	indefinite integral (antiderivative) $\int f(x)dx$	<code>int(k*exp(x)*sin(x), x);</code> <code>int(k*exp(x)*sin(x), k);</code>
<code>int(f(x), x=a..b)</code>	definite integral $\int_a^b f(x)dx$	<code>int(sin(x), x=0..1);</code> <code>int(sin(x), x=0.0..1.0);</code>

- The *Riemann Sums* tutor can be started from the Tools menu:

Tools → Tutors → Calculus - Single Variable → Riemann Sums ...

Note: *The Riemann Sums and Approximate Integrals tutors are identical.*

Related course material/Preparation

§5.1, §5.2, §5.3, and §5.4.

The definite integral of $f(x)$ is defined as the limit of Riemann sums

$$\int_a^b f(x) dx = \lim_{n \rightarrow \infty} \sum_{k=1}^n f(x_k^*) \Delta x.$$

To use the above definition/formula to compute or estimate $\int_a^b f(x) dx$, you first choose n (the number of subintervals) and set $\Delta x = (b - a)/n$ (the length of each subinterval). Next, you need to choose x_k^* in each subinterval. Some popular choices are the left endpoint, the right endpoint, or the midpoint of each subinterval. You then increase n to get better and better approximations. Of course, this leads to messy computations, as there are n terms in the sum and a closed form is in general very hard to find. The **Riemann Sums** tutor is a great tool to carry out those computations. It also let you visualize basic ideas behind the definition.

A completely different way to compute definite integrals is to use the FTC

$$\int_a^b f(x) dx = F(b) - F(a), \quad \text{where } F(x) \text{ is an antiderivative of } f(x).$$

The FTC relates definite integrals (which are numbers as signed areas) to indefinite integrals (which are functions as antiderivatives). This is great if you know how to find $F(x)$. The problem is that, as you likely have learned already, it can be very difficult (or even impossible) to find a closed form of $F(x) = \int f(x)dx$. The Maple is very capable of finding indefinite integrals but don't be surprised when it fails. Just remember that you can always use Riemann sums to find definite integrals numerically.

Assignment

Complete lab activities and your lab instructor will give other assignment for each section

Activities

- Use the **Riemann Sums** tutor to approximate $\int_2^{10} \frac{1}{x} dx$ with the Riemann sum $\sum_{k=1}^4 f(x_k^*) \Delta x$ where:
 - x_k^* is the left endpoint of each subinterval
 - x_k^* is the right endpoint of each subinterval
 - x_k^* is the midpoint of each subinterval

Then increase the number of subintervals and describe what happens to your approximation.

Directions:

- Launch the *Riemann Sums* tutor.
 - Plug in $f(x) = 1/x$, $a = 2$, $b = 10$, and $n = 4$.
 - Click on left and press **Display**. Notice how each rectangle has the height of the left endpoint's function value.
 - Repeat for right and midpoint.
 - Input other values for n , say 8, 64, 200, etc, clicking **Display** each time. What happens to your approximation?
- Use Maple to evaluate $\int_2^{10} \frac{1}{x} dx$ via the FTC and compare it to the results from *Activity 1*.

Step-by-step implementing:

- Define the integrand
`> f := x -> 1/x;`
- Find antiderivative of $f(x)$
`> int(f(x), x);`
- Assign it to F as a function
`> F := x -> label;`
- Apply the FTC `> area:= F(10) - F(2);`

Notes/Remarks:

- The above step-by-step sequence can be replaced by one maple command:
`> int(1/x, x=2..10);`
- To obtain results in decimal, change integral limits, say, 2 and 10, to 2.0 and 10.0.
- As it has been pointed out, one may not be able to find a closed form of $F(x) = \int f(x) dx$. Try the example of $f(x) = (\ln x)e^{-x^2}$ as follows:
`> int(ln(x)*exp(-x^2), x);`
`> int(ln(x)*exp(-x^2), x=2..10);`
 As you can see, maple did not find a closed form of the indefinite integral and hence failed to evaluate the definite integral via the FTC.
- However, if you type in floating-point numbers as the integral limits in `int` command, then maple will evaluate the integral via Riemann sums instead of the FTC. Try the same example but change integral limits to floating-points numbers as follows:
`> int(ln(x)*exp(-x^2), x=2.0..10.0);`

This time it should work, an advantage of Riemann sums over the FTC.

- Repeat *Activity 1* and *Activity 2* for the following definite integrals:

$$\begin{array}{cccc}
 \int_0^{\pi/2} \cos(x) dx & \int_2^6 x^3 dx & \int_{-1}^3 e^{-x} dx & \int_0^4 \frac{x}{x+1} dx \\
 \int_0^1 \cos(\sin(x^2)) dx & \int_0^5 \sqrt{x} dx & \int_{-1}^3 x e^{-x} dx & \int_0^4 \frac{x}{x^4+1} dx
 \end{array}$$
