Abstract

Making use of covering systems and a theorem of D. Shiu, the first and second authors showed that for every positive integer k, there exist k consecutive widely digitally delicate primes. They also noted that for every positive integer k, there exist k consecutive primes which are Brier numbers. We show that for every positive integer k, there exist k consecutive primes that are both widely digitally delicate and Brier numbers.

1. Introduction

In 1958, R. M. Robinson [21] made tables of primes that were of the form $k \cdot 2^n + 1$ for odd integers $1 \le k < 100$ and $0 \le n \le 512$. The table found primes for all of these k except 47. These tables led to a result of W. Sierpiński [23] where he proved there are infinitely many odd positive integers k such that $k \cdot 2^n + 1$ is composite for every positive integer n. Such odd k are called Sierpiński numbers. Sierpiński's proof shows that in fact, for every nonnegative integer m, the number

 $k = 15511380746462593381 + 36893488147419103230 \, m$

is a Sierpiński number. Here, we have added the condition that k is odd in the definition of a Sierpiński number, as is common, though the original paper of Sierpiński did not have such a condition. This added condition arose in part due to the desire to find the smallest Sierpiński number as we explain below.

Since Sierpiński's work, there have been a number of attempts to find small explicit examples of Sierpiński numbers. In 1962, J. Selfridge (see [24]) found the smallest known Sierpiński number, k = 78557. Observe that if we were to remove the condition that k is odd from the definition of a Sierpiński number, then it is likely the number 65536 would be a smaller Sierpiński number. The point here is that, for a positive integer n, the number $65536 \cdot 2^n + 1 = 2^{n+16} + 1$ is a prime only if n+16 is a power of 2. Thus, the number 65536 satisfies $65536 \cdot 2^n + 1$ is composite for all positive integers n if and only if $2^{16} + 1$ is the largest Fermat prime, which is a widely held belief based on heuristic arguments that seems very difficult to prove.

Following the work of Sierpiński [23], Selfridge used what is known as a covering system to prove 78557 is a Sierpiński number; covering systems will be discussed in detail later. While 78857 is the smallest known Sierpiński number, it has not been proven to be the smallest one. Eliminating k as a possible Sierpiński number can be done by finding a prime of the form $k \cdot 2^n + 1$ for some positive integer n, and an effort has been made to find such primes for all odd positive integers k < 78557. In March 2002, there were 17 values of k left to check that are smaller than 78557 and possible Sierpiński numbers. At that time, L. Heim and D. Norris started the Seventeen or Bust project which aimed to prove 78557 is the smallest Sierpiński number (see [19]). The project resulted in showing 11 of the 17 possible Sierpiński numbers less than 78557 are in fact not Sierpiński numbers. Then PrimeGrid took over and showed one more of the remaining possibilities less than 78557 is not a Sierpiński number in October 2016 leaving 5 more possible Sierpiński numbers less than 78557. PrimeGrid has continued to run and, as of February 2021, the remaining possible Sierpiński numbers less than 78557 are 21181, 22699, 24737, 55459, and 67607. If k is one of these five remaining numbers, then PrimeGrid has thus far verified that $k \cdot 2^n + 1$ is composite for all $n \leq 31875742$.

Around the same time that Sierpiński was working with his new class of numbers, Hans Riesel [20] showed there are infinitely many odd integers k such that $k \cdot 2^n - 1$ is composite for every positive integer n. Riesel showed that for every nonnegative integer m, the odd number k = 509203 + 11184810 m has this property. The odd positive integers k with this property are called Riesel numbers.

The number 509203 is conjectured to be the smallest Riesel number (see [26]). The Reisel Sieve Project, analogous to Seventeen or Bust, started in August 2003 to prove the odd positive integers less than 509203 are not Riesel. The project, along with others like PrimeGrid, have reduced the number of possible Riesel numbers k < 509203 down to 48. As of January 2021, PrimeGrid has taken over and shown that these remaining 48 values of k are such that $k \cdot 2^n - 1$ is composite for all

 $n \le 11300000$ (see [26]).

Obtaining Sierpiński and Riesel numbers is typically done by solving a system of linear congruences, where the solution is given in the form of an arithmetic progression. To find such congruences, one makes use of a covering system.

Definition 1 (Covering System). For nonnegative integers a_i and positive integers b_i , the set

$$\{a_1 \pmod{b_1}, a_2 \pmod{b_2}, \ldots, a_m \pmod{b_m}\}$$

is called a covering system (or simply a covering) if for every integer n, we have $n \equiv a_i \pmod{b_i}$ for at least one $i \in \{1, 2, ..., m\}$.

By choosing a_i and b_i as in the definition and choosing p_i prime so that $p_i|(2^{b_i}-1)$ and the p_i 's are distinct, solutions k to the m congruences

$$k \cdot 2^{a_1} + 1 \equiv 0 \pmod{p_1}, \ldots, k \cdot 2^{a_m} + 1 \equiv 0 \pmod{p_m}$$

are Sierpiński, at least for $k > \max_{1 \le i \le m} \{p_i\}$. Similarly, a covering system can be used to obtain Riesel numbers.

In this paper, we will use a covering system argument to obtain Brier numbers, that is, odd positive integers k that are both Sierpiński numbers and Riesel numbers. The existence of such numbers was first established by Brier (see [7]). Brier showed that

29364695660123543278115025405114452910889

is both a Sierpiński and Riesel number.

As was done to obtain Sierpiński and Riesel numbers, Brier found covering systems to determine an arithmetic progression of odd positive integers k for which $k \cdot 2^n + 1$ and $k \cdot 2^n - 1$ are both composite for every positive integer n [1998 unpublished]. In August 2009, A. Wesolowski (see [13]) showed that the smallest Brier number must be larger than 10^9 . The smallest known Brier number is 3316923598096294713661 found by C. Clavier (see [13]) in December 2013. Clavier showed that any number in the arithmetic progression

```
3316923598096294713661 + 3770214739596601257962594704110 m
```

where m is a nonnegative integer, is a Brier number.

One result, which this paper will model its main result after, is the following found in [7].

Theorem 1. For every positive integer k, there exist k consecutive primes all of which are Brier numbers.

The theorem is a consequence of the arithmetic progression above. Since

3316923598096294713661 and 3770214739596601257962594704110

are relatively prime, a result of D. Shiu [22] implies Theorem 1. An extension of Shiu's theorem due to J. Maynard [16] will play an equivalent role in our main result in this paper. Shiu showed that in any arithmetic progression containing infinitely many primes, there are arbitrarily long sequences of consecutive primes [22]. For an arithmetic progression Am + B, where A, B and m are nonnegative integers, to contain infinitely many primes, we want $\gcd(A,B)=1$ and A>0. We see then that Theorem 1 follows from Clavier's arithmetic progression of Brier numbers and Shiu's theorem. The work of Shiu has been strengthened in the work of W. D. Banks, T. Freiberg and C. L. Turnage-Butterbaugh [1] and J. Maynard [16] (also, see T. Freiberg [12]). For example, Maynard extends Shiu's work in Theorem 3.3 of [16] by showing for every positive integer k, in any arithmetic progression Am + B, where A > 0, $B \ge 0$ and $m \ge 0$ are integers with A and B fixed and $\gcd(A,B)=1$, a positive proportion of positive integers ℓ are such that $p_{\ell}, p_{\ell+1}, \ldots, p_{\ell+k-1}$ are all in the arithmetic progression Am + B, where p_j denotes the jth prime.

The main result of this paper not only refers to Brier numbers but also refers to widely digitally delicate primes. First, we define a digitally delicate prime number.

Definition 2 (Digitally Delicate). Let b be an integer ≥ 2 . A prime number is called digitally delicate in base b (or simply digitally delicate for b=10) if changing any base b digit of the prime to another base b digit results in a composite number.

In 1979, P. Erdős [5] proved that there are infinitely many digitally delicate prime numbers. The first of these is 294001. Hence,

d94001, 2d4001, 29d001, 294d01, 2940d1, and 29400d

are composite or equal to 294001 for every $d \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$. The proof of Erdős was done using a partial covering system and a sieve argument. In 2011, Tao [25] was able to refine the sieve part of the argument to show that a positive lower asymptotic density of primes are digitally delicate. Konyagin [15] proved a related result for composite numbers using a similar argument showing that, in particular, a positive lower asymptotic density of composite numbers which are coprime to 10 remain composite if any base 10 digit of the number is changed to another base 10 digit. These authors also establish analogous results for arbitrary bases.

In 2021, the first author and J. Southwick [11] considered a more restrictive class of digitally delicate primes in base 10 and showed a similar result to Tao's for this more restrictive class. These numbers also are required to be composite when changing any one of the infinitely many leading zeroes in base 10.

Definition 3 (Widely Digitally Delicate). Let b be an integer ≥ 2 . A prime number is called widely digitally delicate in base b (or simply widely digitally delicate for b=10) if changing any base b digit of the prime, including any of the infinitely many leading 0's, to another base b digit results in a composite number.

In the same paper [11], the first author and J. Southwick elaborate that the result is possible in some other bases, not just base 10. To see that the collection of widely digitally delicate primes is more refined than digitally delicate primes, consider the digitally delicate prime listed previously, 294001. The prime is not widely digitally delicate since 10294001 is prime. Furthermore, there are no widely digitally delicate primes in the first 10⁹ positive integers [11]. Their result was mentioned in Quanta Magazine [17] along with the next result by the first and third author [7] (also, see [18]). We note that an explicit example of a widely digitally delicate prime has been given by J. Grantham [14] (also, see the comments in [17]). The example has 4030 digits.

Theorem 2. For every positive integer k, there exist k consecutive widely digitally delicate primes.

In this paper, we use the methods from [7] to obtain a result similar to Theorem 2 where the primes are also Brier numbers.

Theorem 3 (Main Theorem). For every positive integer k, there exist k consecutive primes $p_{\ell}, p_{\ell+1}, \ldots, p_{\ell+k-1}$, each of which is both a widely digitally delicate prime and a Brier number. Furthermore, the first primes p_{ℓ} in consecutive lists of k such primes have positive density (depending on k) in the set of prime numbers. In particular, a positive proportion of the primes are both a widely digitally delicate prime and a Brier number.

As a corollary to the proof of Theorem 3, we will also establish the following.

Corollary 1. For every positive integer k, there exist k consecutive primes that are widely digitally delicate in both base 2 and base 10.

2. Some preliminaries and a proof of Corollary 1

In the introduction, we discussed the proof of Theorem 1 based on the use of Shiu's theorem. This included finding an arithmetic progression Am + B where gcd(A, B) = 1 and every number in the arithmetic progression is a Brier number. The goal for establishing Theorem 3 is to construct an arithmetic progression Am + B, with fixed positive relatively prime integers A and B, with A divisible by 10 and having a prime divisor > 10, and with a variable nonnegative integer m, such that every integer k of the form Am + B satisfies

- for every nonnegative integer n and $d \in \{-9, \ldots, -1, 1, \ldots, 9\}$, the number $k + d \cdot 10^n$ is divisible by at least one prime p dividing A,
- for every nonnegative integer n, the number $k \cdot 2^n + 1$ is divisible by at least one prime p dividing A, and

• for every nonnegative integer n, the number $k \cdot 2^n - 1$ is divisible by at least one prime p dividing A.

Provided we can also find such a progression that avoids the expressions $k+d\cdot 10^n$, $k\cdot 2^n+1$ and $k\cdot 2^n-1$ above from being equal to a prime divisor of A, then Theorem 3 will follow directly from Maynard's extension of Shiu's theorem mentioned earlier (i.e., Theorem 3.3 of [16]). Observe that for $m\geq 2$, we have $k\cdot 2^n+1$ and $k\cdot 2^n-1$ are both at least $(2A+B)2^n-1\geq 2A$, which is larger than any prime divisor of A. By replacing B then by 2A+B, we obtain a new arithmetic progression with every element contained in the previous progression, so that the three bulleted items above are still satisfied. Thus, with B so changed, the expressions $k\cdot 2^n+1$ and $k\cdot 2^n-1$ cannot equal a prime divisor of A. The next lemma allows us to adjust A and B further so that the expressions $k+d\cdot 10^n$ in the first bullet above cannot equal a prime divisor of A.

Lemma 1. Let b be an integer ≥ 2 . Let A and B be positive relatively prime integers such that A has a prime divisor > b and every prime dividing b divides A. Suppose further that for every nonnegative integers m and k and for

$$d \in \{-(b-1), -(b-2), \dots, -1\} \cup \{1, 2, \dots, b-1\},\$$

there is a prime p dividing A which also divides $Am + B + d \cdot b^k$. Then, a subprogression $A_0m + B_0$ can be found, with A_0 and B_0 relatively prime and A dividing A_0 , such that for every nonnegative integers m and k and for d as above, there is a prime p dividing A_0 with

$$p \mid (A_0 m + B_0 + d \cdot b^k)$$
 and $A_0 m + B_0 + d \cdot b^k \neq \pm p$.

Proof. Let A' be the largest positive integer dividing A that is relatively prime to b. Then there is a positive integer u such that A divides $b^u A'$. Furthermore, taking $v = \phi(A')$ and a positive integer $\ell \ge u$, we see that A divides $b^{\ell(v+1)} - b^{\ell}$. We take $\ell \ge \max\{u, 2\}$ sufficiently large so that also $b^{\ell} > A + B$, and set

$$A_0 = b^{\ell(v+2)}A$$
 and $B_0 = b^{\ell(v+1)} - b^{\ell} + B$.

Note that $\ell \geq 2$ ensures that $\ell(v+1)-1 \geq 2\ell-1 \geq \ell+1$, which we use momentarily. Since A divides $b^{\ell(v+1)}-b^{\ell}$, we see that for every nonnegative integer m, there is a nonnegative integer m' such that $A_0m+B_0=Am'+B$, so the arithmetic progression A_0m+B_0 is a subprogression of the arithmetic progression Am+B. By the properties of the progression Am+B, we deduce that for every nonnegative integers m and k and for $d \in \{-(b-1), -(b-2), \ldots, -1\} \cup \{1, 2, \ldots, b-1\}$, there is a prime p dividing A, and hence A_0 , with $p \mid (A_0m+B_0+d\cdot b^k)$. Furthermore, if $k \leq \ell(v+1)-1$, we see that

$$A_0m + B_0 + d \cdot b^k = b^{\ell(\nu+2)}Am + b^{\ell(\nu+1)} - b^{\ell} + B + d \cdot b^k$$

$$\geq b^{\ell(v+1)} - b^{\ell} + B - (b-1)b^{\ell(v+1)-1}$$

$$= b^{\ell(v+1)-1} - b^{\ell} + B \geq b^{\ell+1} - b^{\ell} + B$$

$$> b^{\ell} > A$$

for every nonnegative integer m. Also, if $k \geq \ell(v+1)$, then $k \geq 2\ell$ so that

$$A_0m + B_0 + d \cdot b^k \equiv -b^\ell + B \pmod{b^{2\ell}}.$$

Since $b^{\ell} > A + B$, we see that

$$-b^{2\ell} + A < b^{\ell} - b^{2\ell} < -b^{\ell} < -b^{\ell} + B < -A.$$

In this case, $A_0m + B_0 + d \cdot b^k$ is in a residue class modulo $b^{2\ell}$ represented by an integer in $(A, b^{2\ell} - A)$. In both cases, that is $k \leq \ell(v+1) - 1$ and $k \geq \ell(v+1)$, we deduce that since $p \leq A$, we have $A_0m + B_0 + d \cdot b^k \neq \pm p$.

As noted before Lemma 1, we will find an arithmetic progression Am + B, with $10 \mid A$ and A divisible by a prime > 10, satisfying the bullets above. The comments before Lemma 1 together with Lemma 1 with b = 10 allow us to find a subprogression of Am + B such that every prime k in the subprogression is both widely digitally delicate and a Brier number. Maynard's extension of Shiu's theorem will then imply Theorem 3.

We are now ready to prove Corollary 1.

Proof of Corollary 1 (assuming the existence of Am + B as above). To establish a prime k is widely digitally delicate in base 2, it suffices to show $k \pm 2^n$ is composite for all nonnegative integers n. Let k = Am + B, with A and B as above and m a nonnegative integer. Fix a nonnegative integer n. Let

$$T = n \prod_{p|A} (p-1).$$

Then by the second bullet above, there is a prime p dividing A such that

$$(Am + B) \cdot 2^{T-n} + 1 \equiv 0 \pmod{p}.$$

Note that this congruence implies p is odd. Since $2^T \equiv 1 \pmod{p}$, we deduce

$$(Am + B) \cdot 2^{-n} + 1 \equiv 0 \pmod{p}.$$

Multiplying both sides of the congruence by 2^n gives

$$k + 2^n \equiv 0 \pmod{p}$$
.

Thus, for each nonnegative integer n, the number $k + 2^n$ is divisible by a prime dividing A. Similarly, for each nonnegative integer n, we can see that the third

bullet above implies that the number $k-2^n$ is divisible by a prime dividing A. By applying Lemma 1 first with b=10 and then with b=2, we see that there is a subprogression of Am+B containing infinitely many primes such that every prime in the subprogression is widely digitally delicate in both base 10 and base 2. Shiu's theorem applies as before to complete the proof.

3. The coverings

As explained in the previous section, we are interested in finding an arithmetic progression Am + B, with gcd(A, B) = 1 and with A divisible by 10 and some prime > 10, satisfying the bulleted items at the beginning of the previous section. By replacing A with a power of A, we may suppose that B < A and do so. We will refer to properties (i), (ii) and (iii) analogous to the bullets of the previous section as follows.

(i) If
$$d \in \{-9, -8, \dots, -1\} \cup \{1, 2, \dots, 9\}$$
, then each number in the set
$$\mathcal{A}_d = \mathcal{A}_d(A, B) = \{Am + B + d \cdot 10^n : m \in \mathbb{Z}^+ \cup \{0\}, \ n \in \mathbb{Z}^+ \cup \{0\}\}$$

is composite.

(ii) Each number in the set

$$\mathcal{B}_S = \mathcal{B}_S(A, B) = \{ (Am + B) \cdot 2^n + 1 : m \in \mathbb{Z}^+ \cup \{0\}, \ n \in \mathbb{Z}^+ \cup \{0\} \}$$

is composite.

(iii) Each number in the set

$$\mathcal{B}_R = \mathcal{B}_R(A, B) = \{ (Am + B) \cdot 2^n - 1 : m \in \mathbb{Z}^+ \cup \{0\}, \ n \in \mathbb{Z}^+ \cup \{0\} \}$$

is composite.

In the above, a negative integer is composite if its absolute value is composite.

The statement (i) is exactly the condition we want for each prime in the progression Am + B to be widely digitally delicate. Similarly, (ii) and (iii), imply that each prime in the progression Am + B is a Sierpiński number and Riesel number, respectively.

Note that we want relatively prime A and B satisfying (i), (ii), and (iii). However, we go about this indirectly by finding relatively prime A_1 and B_1 so that each number in $\mathcal{A}_d(A_1, B_1)$ is composite, by finding relatively prime A_2 and B_2 so that each number in $\mathcal{B}_S(A_2, B_2)$ is composite, and by finding relatively prime A_3 and B_3 so that each number in $\mathcal{B}_R(A_3, B_3)$ is composite. Thus, for example, every positive

integer that is B_1 modulo A_1 is such that if we add $d \cdot 10^n$ to the integer, where $n \in \mathbb{Z}^+ \cup \{0\}$ and $d \in \{-9, -8, \dots, -1\} \cup \{1, 2, \dots, 9\}$, the resulting number is composite.

Let

$$\mathcal{P}(A) = \{p : p \text{ is prime and } p|A\}.$$

We will take each of A_1 , A_2 , and A_3 to be a product of distinct primes. In other words, each A_j is squarefree. The A_j 's and B_j 's will have the properties

$$\mathcal{P}(A_1) \cap \mathcal{P}(A_2) = \emptyset, \quad \mathcal{P}(A_1) \cap \mathcal{P}(A_3) = \emptyset, \quad \mathcal{P}(A_2) \cap \mathcal{P}(A_3) = \{2, 5\},$$

$$B_2 \equiv B_3 \pmod{10}.$$
(1)

By applying the Chinese Remainder Theorem, we can then establish (i), (ii), and (iii) for some relatively prime A and B by taking $A = A_1A_2A_3/10$ and $B \in [0, A-1]$ so that

$$B \equiv B_1 \pmod{A_1}, \quad B \equiv B_2 \pmod{A_2/10}, \quad B \equiv B_3 \pmod{A_3/10}, B \equiv B_2 \equiv B_3 \pmod{10}.$$
 (2)

The first and third authors [7] constructed A_1 squarefree and B_1 so that (i) holds with $\mathcal{A}_d(A,B)$ replaced by $\mathcal{A}_d(A_1,B_1)$. Thus, this paper will focus on constructing the pair (A_2,B_2) as well as the pair (A_3,B_3) such that (1) holds and (ii) and (iii) hold with $\mathcal{B}_S(A,B)$ and $\mathcal{B}_R(A,B)$ replaced by $\mathcal{B}_S(A_2,B_2)$ and $\mathcal{B}_R(A_3,B_3)$, respectively.

Since the construction of the pairs (A_2, B_2) and (A_3, B_3) is similar, we will discuss the construction of the pair (A_2, B_2) and then explain how this translates to constructing the pair (A_3, B_3) . To show that $(A_2m + B_2) \cdot 2^n + 1$ is composite for all nonnegative integers n, we will show that for each nonnegative integer n, there is a prime, $p \in \mathcal{P}(A_2)$ such that p divides $(A_2m + B_2) \cdot 2^n + 1$. We will choose A_2 and B_2 large enough so that each number of the form $(A_2m + B_2) \cdot 2^n + 1$, with m and n in $\mathbb{Z}^+ \cup \{0\}$, is greater than each prime in $\mathcal{P}(A_2)$. Thus, every number of the form $(A_2m + B_2) \cdot 2^n + 1$ will be composite.

For a prime $p \in \mathcal{P}(A_2)$, observe that $(A_2m + B_2) \cdot 2^n + 1$ is divisible by p if and only if $B_2 \cdot 2^n + 1$ is divisible by p. Initially, we do not know the values of A_2 and B_2 ; we want to construct them. The idea then is to find a finite set \mathcal{P}_2 of primes so that for some positive integer B_2 and all nonnegative integers n, the number $B_2 \cdot 2^n + 1$ is divisible by one of the primes in \mathcal{P}_2 . Then A_2 will be determined by taking A_2 to be the product of the primes in \mathcal{P}_2 so that $\mathcal{P}(A_2) = \mathcal{P}_2$. We want to construct B_2 as above in such a way that $\gcd(A_2, B_2) = 1$. The focus now is on finding the set \mathcal{P}_2 and how to construct B_2 from this set.

For an odd prime p and an arbitrary integer a, we can determine $B_2 \equiv -2^{-a} \pmod{p}$ so that

$$B_2 \cdot 2^n + 1 \equiv 0 \pmod{p},$$

when $n \equiv a \pmod{b}$ with $b = \operatorname{ord}_p(2)$. The idea now is to determine primes p (our set \mathcal{P}_2) so that the orders of 2 modulo these primes and appropriate choices for a as above provide us with a list of congruence classes $n \equiv a \pmod{b}$ that form a covering system for the integers. In this way, for every nonnegative integer n, there will be a prime p such that p divides $B_2 \cdot 2^n + 1$, where p depends on a congruence class satisfied by n.

We now use an example to illustrate how a congruence class in the covering system gives a congruence class for B_2 to satisfy. We take p=5. The order of 2 modulo 5 is 4, so the modulus for the congruence on n will be 4. Suppose we want the congruence $n \equiv 0 \pmod{4}$ in the covering system for n. If we let $B_2 \equiv -2^{-0} \equiv 4 \pmod{5}$, then for some integer t, we have

$$B_2 \cdot 2^n + 1 = B_2 \cdot 2^{4t} + 1 \equiv 4 \cdot 1 + 1 \equiv 0 \pmod{5}.$$

Thus, whenever $n \equiv 0 \pmod{4}$, the number $B_2 \cdot 2^n + 1$ is divisible by 5. Then $n \equiv 0 \pmod{4}$ is part of the covering system we want to help establish (ii), where we want

$$A_2 \equiv 0 \pmod{5}$$
 and $B_2 \equiv 4 \pmod{5}$.

In order for (1) to hold, observe that we need $5 \notin \mathcal{P}(A_1)$. The value of A_1 is given in [7], and throughout this paper, we avoid using primes in $\mathcal{P}(A_1)$. It is the case that $5 \notin \mathcal{P}(A_1)$, so using 5 as above is permissible. We note that the primes 2 and 5 were not in $\mathcal{P}(A_1)$ because, in [7], the authors were interested in choosing moduli for the coverings based on the order of 10 modulo the primes dividing A_1 . This led them to avoiding the primes 2 and 5 for which no such order exists. Similarly in this paper, we will want 2 to have an order modulo each of the primes dividing A_2 or A_3 , and thus we will seemingly want to avoid the prime 2. However, we have already indicated that we want $A_j m + B_j$ to be odd for $j \in \{2,3\}$, so we are taking 2 to be in both $\mathcal{P}(A_2)$ and $\mathcal{P}(A_3)$ with the added conditions that B_2 and B_3 are 1 modulo 2.

Now, suppose we want to show that $(A_2m + B_2) \cdot 2^n + 1$ is composite as in (ii) whenever $n \equiv 2 \pmod{4}$. Since 5 is the only prime p with 2 of order 4 modulo p, the idea is to work modulo 8 instead and show that $(A_2m + B_2) \cdot 2^n + 1$ is composite when $n \equiv 2 \pmod{8}$ and when $n \equiv 6 \pmod{8}$. Each of these will require a number of congruence classes, particularly since we want to avoid primes in $\mathcal{P}(A_1)$ and the only prime p with 2 of order 8 modulo p is $p = 17 \in \mathcal{P}(A_1)$. For the discussion now, we consider the case of showing $(A_2m + B_2) \cdot 2^n + 1$ is composite when $n \equiv 2 \pmod{8}$.

By the above arguments, we want to find primes so that if B_2 satisfies certain congruence classes, then whenever $n \equiv 2 \pmod{8}$, one of these primes divides $B_2 \cdot 2^n + 1$. The primes we found are given in the second column in Table 1. Momentarily, we will describe how we determined the primes more clearly, but if $n \equiv a \pmod{b}$ and p are the columns in a row of Table 1, then the order of 2

modulo p is b. To see that every integer $n \equiv 2 \pmod 8$ satisfies a congruence class in the first column, observe that if $n \equiv 128 \pmod {144}$, then n satisfies one of the last 3 congruence classes in the first column of Table 1. With the prior two congruence classes modulo 144, every $n \equiv 42 \pmod {48}$ will satisfy one of the last 5 congruence classes in the first column. If $n \equiv 74 \pmod {96}$, then it satisfies one of the congruence classes in rows 4-6 in the first column. Thus, if $n \equiv 26 \pmod {48}$, then it satisfies one of the congruence classes in rows 3-6 in the first column. Now, if $n \equiv 10 \pmod {16}$, then it satisfies one of the congruence classes in rows 2-10 in the first column. Since integers which are 2 modulo 16 satisfy the first congruence class in the first column, we see that every integer $n \equiv 2 \pmod {8}$ satisfies at least one congruence class in the first column of Table 1.

Table 1: Congruence classes used to satisfy $n \equiv 2 \pmod{8}$

Congruence class	prime
$n \equiv 2 \pmod{16}$	257
$n \equiv 10 \pmod{48}$	673
$n \equiv 26 \pmod{96}$	22253377
$n \equiv 74 \pmod{288}$	1153
$n \equiv 170 \pmod{288}$	6337
$n \equiv 266 \pmod{288}$	38941695937
$n \equiv 42 \pmod{144}$	577
$n \equiv 90 \pmod{144}$	487824887233
$n \equiv 138 \pmod{432}$	4261383649
$n \equiv 282 \pmod{432}$	209924353
$n \equiv 426 \pmod{432}$	24929060818265360451708193

So we will choose A_2 so that it is divisible by each prime in the second column of Table 1. Corresponding to each congruence $n \equiv a \pmod{b}$ and prime p in a row, we take $B_2 \equiv -2^{-a} \pmod{p}$ as noted earlier. Then whenever $n \equiv 2 \pmod{8}$ and $m \in \mathbb{Z}$, we have $(A_2m + B_2) \cdot 2^n + 1$ is divisible by a prime in the second column of Table 1.

Next, we describe more clearly where our choice of primes came from. The idea in the example above is to find a system \mathcal{C} of congruence classes such that every $n \equiv 2 \pmod{8}$ satisfies a congruence $n \equiv a \pmod{b}$ in \mathcal{C} . Each such congruence class will correspond to a prime $p \notin \mathcal{P}(A_1)$ for which 2 has order b modulo p. To find the primes p for which 2 has order b modulo p, where b is a modulus we want to use for \mathcal{C} , we look at the prime divisors of $\Phi_b(2)$, where $\Phi_b(x)$ is the b^{th} cyclotomic polynomial. As noted in [7] and [10] (with 2 replaced by 10), each prime divisor p of $\Phi_b(2)$ either will be the largest prime divisor of p or will satisfy that 2 has order p modulo p. Thus, looking at prime divisors of p of p or will are not in p of p determines whether we can use the modulus p for p and how many times we can

use b as a modulus. Thus, in general, we found what moduli were possible for our systems of congruence classes by looking at the number of distinct prime divisors of $\Phi_b(2)$, not in $\mathcal{P}(A_1)$, for different choices of b, and then we determined our covering systems based on this information.

Observe in Table 1 that we could have interchanged the primes with 2 of a given order b. For example, for the congruences $n \equiv 74 \pmod{288}$, $n \equiv 170 \pmod{288}$, and $n \equiv 266 \pmod{288}$, we could have selected the primes in the right-most column as 38941695937, 1153, and 6337, respectively.

Tables 3 and 4 describe the results of looking at prime factors of $\Phi_b(2)$ to determine the moduli b we can use for our covering systems and the number of times we can use each modulus (that is, the number of distinct prime factors of $\Phi_b(2)$ that do not divide b and are not in $\mathcal{P}(A_1)$). Table 3 indicates the number of distinct prime factors of $\Phi_b(2)$ that do not divide b and are not in $\mathcal{P}(A_1)$ but are in $\mathcal{P}(A_2) \cup \mathcal{P}(A_3)$. Table 4 shows the remaining number of distinct prime factors of $\Phi_b(2)$ which we know exist and do not divide b and are not in $\mathcal{P}(A_1)$ for each modulus. If a modulus b appears in Table 3 but not in Table 4, then all the distinct prime factors of $\Phi_b(2)$ that do not divide b and are not in $\mathcal{P}(A_1)$ have been used in $\mathcal{P}(A_2) \cup \mathcal{P}(A_3)$.

The above describes how we obtained a covering system for determining A_2 and B_2 so that (ii) holds. We obtain a covering system for determining A_3 and B_3 similarly so that (iii) holds. In this case, each congruence $n \equiv a \pmod{b}$ corresponds to an odd prime p dividing A_3 , with b equal to the order of 2 modulo p, and we want

$$B_3 \equiv 2^{-a} \pmod{p} \tag{3}$$

so that

$$B_3 \cdot 2^n - 1 \equiv 0 \pmod{p}$$

for $n \equiv a \pmod{b}$.

For p = 5 above, we took $B_2 \equiv 4 \pmod{5}$. Also, B_2 is odd, so we have $B_2 \equiv 9 \pmod{10}$. For (1) to hold, we therefore want $B_3 \equiv 9 \pmod{10}$. In particular, $B_3 \equiv 4 \pmod{5}$. From (3), with p = 5, we want a = 2. As the order of 2 modulo 5 is 4, the congruence we want associated with p = 5 and (iii) is $n \equiv 2 \pmod{4}$.

Each prime counted in Table 3 in the last column, besides p=5 with b=4, can be used to provide a congruence class for the covering system corresponding to either (ii) or (iii) and not both, due to the restriction made in (1) that $\mathcal{P}(A_2) \cap \mathcal{P}(A_3) = \{2, 5\}$. The complete covering systems used for determining A_j and B_j , for $j \in \{2, 3\}$, can be found in the appendix. In the next section, we explain how we verified that the congruence classes we tabulated for the covering systems in fact form covering systems.

4. Verifying the Covering Systems

Consider the collection of congruence classes

$$C_0 = \{0 \pmod{3}, 1 \pmod{3}, 2 \pmod{9}, 5 \pmod{9}, 8 \pmod{9}\}.$$

We can verify C_0 is a covering system as follows. Every nonnegative integer is either 0, 1 or 2 (mod 3). The congruence classes 0 (mod 3) and 1 (mod 3) are in C_0 , so the case when an integer is 2 (mod 3) is left to satisfy. Every integer that is 2 (mod 3) is either 2 (mod 9), 5 (mod 9), or 8 (mod 9). These congruence classes modulo 9 are in C_0 . Thus, C_0 is a covering system.

Due to the complexity of the coverings in the previous section, this method for verifying in general a

$$C = \{a_1 \pmod{b_1}, a_2 \pmod{b_2}, \dots, a_m \pmod{b_m}\}$$

is a covering is quite time consuming. An alternate way of verifying \mathcal{C} is a covering is to check every integer in $[0, \ell - 1]$, where $\ell = \text{lcm}(b_i)$. To see this, suppose that every integer in $[0, \ell - 1]$ is in at least one congruence class in \mathcal{C} . We want to show that all integers k are in at least one congruence class in \mathcal{C} . We can rewrite k as

$$k = q \cdot \ell + r$$

where q and r are integers with $0 \le r \le \ell - 1$. Since $r \in [0, \ell - 1]$, we have that r is in at least one congruence class, $a \pmod{b}$, in \mathcal{C} . As a consequence of b dividing ℓ , we deduce

$$k \equiv r \equiv a \pmod{b}$$
.

Thus, k is in the congruence class $a \pmod{b}$ in C, as we wanted.

In the example above with C_0 , this process is emulated by checking that every $k \in [0, 8]$ satisfies a congruence class in C_0 . Table 2 confirms that C_0 is a covering by listing a congruence class each k satisfies in C_0 in the second column.

While this method works and is easily implemented by a computer, if $\ell = \text{lcm}(b_i)$ is too large, this process takes a substantial amount of time. In the coverings used in this paper for Sierpiński and Riesel numbers, the least common multiples are 236107872000 and 922078080000, respectively. Also, the number of congruence classes in the coverings are 447 and 459, respectively. Thus, an alternative verification method, as seen in the paper [7], was used.

Let \mathcal{C} be a set of congruence classes $a_i \pmod{b_i}$. Let w be a positive integer and u be an integer in [0, w-1]. Let \mathcal{C}_u be the congruence classes $a_i \pmod{b_i}$ in \mathcal{C} such that

$$a_i \equiv u \pmod{\gcd(b_i, w)}$$
.

Congruence Classes in \mathcal{C}_0 0 $0 \pmod{3}$ 1 $1 \pmod{3}$ 2 $2 \pmod{9}$

Table 2: Verifying the Covering C_0

3 $0 \pmod{3}$ 4 $1 \pmod{3}$ 5 $5 \pmod{9}$ 6 $0 \pmod{3}$

 $1 \pmod{3}$

 $8 \pmod{9}$

If $|\mathcal{C}_u| = 0$, then \mathcal{C} is not a covering. Now consider the case that $|\mathcal{C}_u| > 0$. Let ℓ' be the lcm of the moduli in C_u , and set $d = \gcd(w, \ell')$. In [7], the authors show the following.

Lemma 2. With the above notation, if for each $u \in [0, w-1]$, every

$$k = wt + u$$
, with $t \in [0, (\ell'/d) - 1] \cap \mathbb{Z}$,

satisfies a congruence class in C_u , then C is a covering system.

7

8

Let \mathcal{C} be one of the systems of congruence classes created in the previous section, that is for constructing arithmetic progressions for either Sierpiński or Riesel numbers. We take $w = 4 \cdot 3 \cdot 5 \cdot q$ where q is the largest prime dividing the least common multiple of the moduli in \mathcal{C} as done in [7]. Applying Lemma 2 with this choice of w allowed us to easily verify our congruence classes form a covering system.

Appendix

To aid in verifying the computations in this paper, all the data in this appendix can be found in [9] as lists suitable for computations. This appendix begins with Table 3, which lists the number of distinct primes used, L = L(b), that divide $\Phi_b(2)$, do not divide b, and are not in $\mathcal{P}(A_1)$. Not the * indicates the prime 5 is used once in each covering. The b listed correspond to moduli used in our coverings. Table 4 gives a lower bound on number of distinct primes, M = M(b), that divide $\Phi_b(2)$, do not divide b, are not in $\mathcal{P}(A_1)$, and are not used in either covering. The * in this table represents an M(b) that is a lower bound; that is, we did not completely factor $\Phi_b(2)$.

Tables 5 and 6 list the congruence classes $n \equiv a \pmod{b}$ that form the covering systems we obtained for $k \cdot 2^n + 1$ and $k \cdot 2^n - 1$ respectively. Recall that, with the order b of 2 fixed, the choice of a prime p associated with a given congruence class does not matter. Thus, for example, $\Phi_{64}(2)$ has exactly two prime factors, 641 and 6700417, neither of which are in $\mathcal{P}(A_1)$. These two primes are in the count for L(64) in Table 3. We associate some ordering of these two primes. The second column of Table 5 indicates that one of these primes is associated with the congruence $n \equiv 22 \pmod{64}$ and the other is associated with the congruence $n \equiv 54 \pmod{64}$. Note that we do not attempt to clarify which of the two primes is associated with which congruence as it does not matter.
